The Generalised Linear Model (2)

PSM 2

Bennett Kleinberg

22 Jan 2019

Welcome

Probability, Statistics & Modeling II

Lecture 3

GLM₂

What question do you have?

Today

- Recap linear regression
- Why the GLM?
- Extended cases: logistic regression
- How good is the model?
- How does one model compare to another?

Recap linear regression

Ingredients?

Recap linear regression Core idea?

Recap linear regression Types of effects?

Recap linear regression Residuals?

Continuation from last week

How to find the "optimal" terms for my model?

Maybe we can optimise this?

What if you don't know what the 'ideal' model is?

Especially neat for predictive modelling

**Back to the shooting data: **

```
smsd = smsd[smsd$school_related != 'Killed', ]
load('./data/mass_shootings_detailed.RData'
                                                                                 smsd = droplevels(smsd)
                                                                                                                             names (smsd
```

```
"date"
"n\_injured"
               "gender"
                            "school_related" "mental illness"
"n_fatal"
"caseid"
              "day"
```

Automated variable selection

1. Specify the complete model

```
complete_model = lm(n_fatal ~ n_guns*mental_illness*school_related, data
```

2. Specify the null model

```
null_model = lm(n_fatal ~ 1, data = smsd)
```

3. Run model selection ...

3 predictor variables: how many terms in the model?

- 1 intercept
- 3 main effects
- 3 2-way interactions
- 1 3-way interaction

Model selection

```
summary(complete_model)
```

```
.90.0
                                                                                                                                              Estimate Std. Error t valu

Limitations of linear regression?

- Correlation!= causation
- Continuous outcome variable

Generalising the model The Generalised Linear Model

GLM in general

- framework to deal with different outcome variables
- uses the same "linearity in parameters" idea
- key feature: linking the outcome to the predictor(s)

The GLM in R

```
rela
 n guns*mental illness*school
my_model_glm = glm(formula = n fatal
                      family = gaussian

```

GLM vs LM

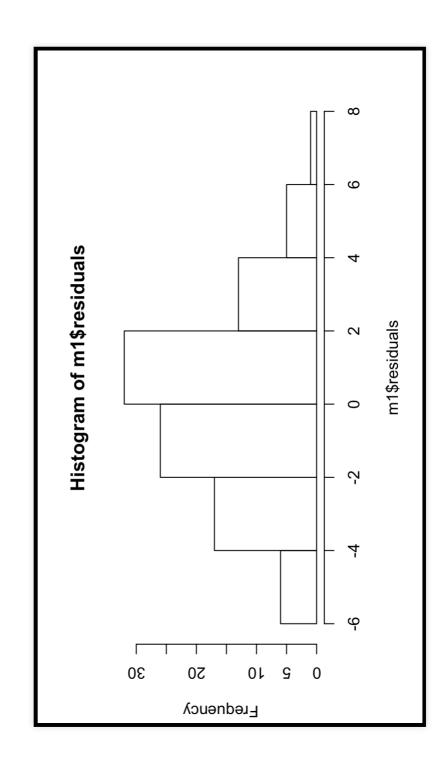

The LM is a GLM with the Gaussian link function.

- link function 'links' the linear predictor to the mean of the distribution of the outcome variable
- e.g. if outcome variable from normal distribution -> "normal" link function (Gaussian)
- e.g. if outcome variable from poisson distribution -> "Poisson" link (Log)
- e.g. if outcome variable from binomial distributiob -> "Binomial" link (Logit)

Why bother with this?

```
df1 = data.frame(a1 = 1:100, b1)
{plot(b1)
abline(lm(b1 ~a1, data=df1))}
```

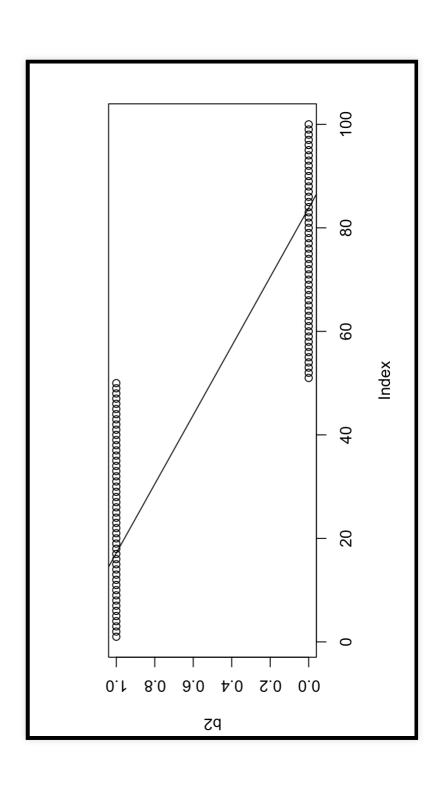

m1 = lm(b1 ~a1, data=df1)
hist(ml\$residuals)

Why bother with this?

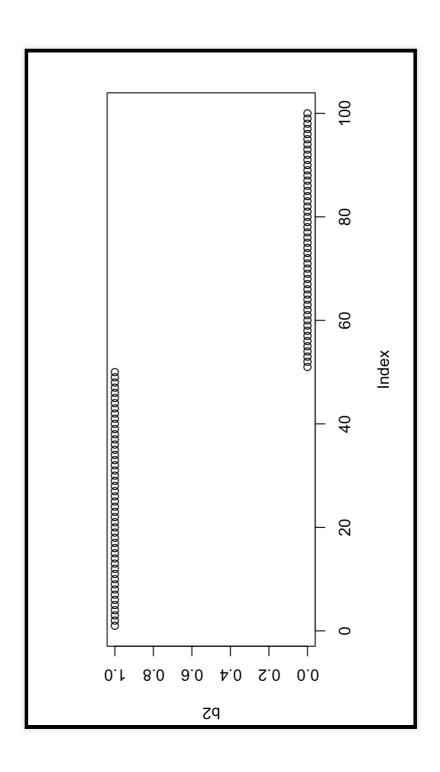

Compare:

```
b2 = rep(c(1,0), each=50)
df2 = data.frame(a2 = 1:100, b2)
                                       {plot(b2)
abline(lm(b2 ~a2, data=df2))}
```

0.4 Histogram of m2\$residuals m2\$residuals ١0 8 7 0 ゎ 9 Þ Frequency

m2 = lm(b2 ~a2, data=df2)
hist(m2\$residuals)

What to do?

We need a representation of the outcome variable...

that is linear to the predictor

i.e. transforms the data to so that Y has a linear relationship to the predictors

But which function does this?

The link function

Answer: for binary outcomes, the logit function

- transforms the outcome to a continuous probability
- and uses the log-odds to model a linear relationship between X and Y

The logit function

```
 maps 0, 1 values to -Inf:
```

- assumes a probability of P(Y ==
- probability is expressed as the odds
- linearity through the log of the odds

```
prob = 0.40
odds = prob/(1+prob)
```

```
# [1] 0.2857143
```

```
log(odds)
```

```
## [1] -1.252763
```

Intermezzo: odds

	Smoker	Smoker Nonsmoker
Dead	30	Dead 30 20
Alive	70	80
	100	100 100

#Odds of smoker dead: (30/100)/(70/100)

[1] 0.4285714

equal to 30/70

[1] 0.4285714

Odds = event_present/event_not_present

٨

odds = P/(1-P)

	Smoker	Smoker Nonsmoker
Dead	30	Dead 30 20
Alive	70	80
	100	100 100

Odds of nonsmoker alive?

	Smoker	Smoker Nonsmoker
Dead	30	20
Alive	70	Alive 70 80
	100	100 100

#Odds of nonsmoker alive: 80/20

[1] 4

	Smoker	Nonsmoker
Dead	30	Dead 30 20
Alive	70	Alive 70 80
	100	100 100

Odds of nonsmoker alive dead?

	Smoker	Smoker Nonsmoker
Dead	30	Dead 30 20
Alive	70	Alive 70 80
	100	100 100

Odds of nonsmoker alive dead?

20/80

[1] 0.25

1/(80/20)

[1] 0.25

	Smoker	Nonsmoker
Dead	30	Dead 30 20
Alive	70	Alive 70 80
	100	100 100

Odds ratio: association between both factors.

OR = (30/70)/(20/80)

[1] 1.714286

The logit function

Models the binary outcome through the log odds of the predictors.

mplication: transformation of the coefficients

Remeber: we model the log of the odds ratio.

The logit function

Implication: transformation of the coefficients

Remeber: we model the log of the odds ratio.

So we need to 'unlog' the coefficients to get the odds.

Case today: Parole data

## 2.391896 -1.363046
```

What would the Im interpretation be?

Coefficient interpretation

Remember what the logit function does?

Y ~ log_odds_ratio(X)

... So the coefficient x needs to be transformed.

Coefficient interpretation

Transforming the coefficient:

log odds to probability

- log -> un-log
- natural logarithm reverse
- e -> exp() in R

Coefficient interpretation

Let's use the output and transform:

```
coefficients(parole_success)
                                                   SEXMALE
                                                                    -1.363046
                                                                  2.391896
                                                  ## (Intercept)
```

```
## [1] 0.2566608
\exp(-1.36)
```

Understanding the odds

table(parole_data\$granted, parole_data\$sex)

```
## FEMALE MALE
## 0 228 10220
## 1 2493 28594
```

Odds by hand

	Female Male	Male	
0		10220	
\leftarrow	1 2493	28594	
	2721 38814	38814	

Odds of male granted:

(28594/38814)/(10220/38814)

[1] 2.797847

#Note: equivalent to 28594/10220

Odds of female granted:

2493/228

[1] 10.93421

```

```
## [1] -50.7433
```

Mean absolute percentage error

mean(abs(complete_model\$residuals/(complete_model\$model\$n_fatal+1))*100)

[1] 75.17279

When to choose one model over the other?

Idea: 2 models compete

Requirement: the two models are nested

Nested models

```
model_2 = lm(n_fatal ~ mental_illness+school_related, data = smsd)
                                                                    data = smsd
                                                                  model 3 = lm(n_fatal ~ mental_illness*school_related,
~ mental_illness, data = smsd)
 lm(n_fatal
 model
```

Rough model evaluation

```
sqrt(mean(model_1$residuals^2))
                                                                                                                                                                                                                                                                                                                       sqrt(mean(model_3$residuals^2))
                                                                                                                                                            sqrt(mean(model_2$residuals^2))
                                                                                                                                                                                                                                                                                                                                                                                                     ## [1] 4.306262
